

## Supporting information:

**Authors:** Jose B. Lanuza, Romina Rader, Jamie Stavert, Liam K. Kendall, Manu E. Saunders, Ignasi Bartomeus

*The following Supporting Information is available for this article:*

**Appendix S1.** Brief description of the different traits and categories compiled in this study divided in reproductive, floral and vegetative traits.

**Table S1.** List of the 28 plant-pollinator studies used to build the plant trait database.

**Table S2.** Loadings of the first three principal components of the phylogenetic informed principal component analysis with all species.

**Table S3.** Loadings of the first three principal components of the phylogenetic informed principal component analysis with the subset of species with data of nectar and pollen quantity.

**Table S4.** Statistical association of the different categorical variables to the principal components one and three from the pPPCA with the full set of species.

**Table S5.** Phylogenetic signal of the different quantitative traits.

**Figure S1** Percentage of present and missing values of the different variables.

**Figure S2** Phylogenetic informed principal component analysis for the species that did not have missing values.

**Figure S3** Fitted posterior estimates of the number of visits made by bees including and excluding honey bees on the main axes of trait variation.

**Figure S4** Regression tree comparison between the regression trees with the full set of species and with the subset of species with floral rewards.

**Figure S5** Trait relationship of PC1 and PC3 with the phylogenetic informed principal component analysis with the full set of species.

**Figure S6** Phylogenetic informed principal component analysis for the imputed dataset of the subset of species with quantitative information of nectar and pollen.

**Figure S7** Statistical comparison of the different categories of the categorical traits on the main two axes of trait variation (pPCA with the full set of species).

**Figure S8** Fitted posterior estimates of the number of visits made by the main functional groups of bees on the main axes of trait variation.

**Figure S9** Sum of visits per plant, normalized degree and specialization modelled in function of the first three main axes of trait variation.

## Appendix S1

Brief description of the different traits and categories compiled in this study divided in reproductive, floral and vegetative traits.

### *Reproductive traits*

- Breeding system: The different plant species were classified in hermaphrodite, dioecious and monoecious species. Intermediate breeding systems or more complex ones were also annotated but all the species were divided into these three main categories for simplicity of the analysis.
- Selfing level: We recorded the selfing level of the different species with both quantitative and qualitative data. The qualitative data was divided in four main categories, high selfers, medium selfers, low selfers and none which was for the species that were unable to self-pollinate. In addition, quantitative data was also divided into these four categories with the following criteria: from 0% to lower than 1% ‘none’, from 1% to 25% ‘low’, from 26% to 75% ‘medium’ and from 76% to 100% ‘high’. We opted for the metric of autonomous selfing because it was the most abundant one in the literature and more complex metrics that were more informative were scarce.
- Compatibility system: The different species were divided in three main categories in order to know their ability to self-pollinate. These categories were self-compatible, partially self-compatible and self-incompatible species. The field of selfing level is partly complementary to the compatibility system but is important to note that not all the self-compatible species or partially self-compatible species will self-pollinate.

### *Floral traits*

- Flower morphology: We looked for images and illustrations of the flowers from the different species on the floras and available resources in order to categorize the flower shape. We divided the flowers in 8 main different categories: open, tube, campanulate,

funnelform, papilionaceous, spike and capitulum. See image X for the different flower morphologies.

- Flower symmetry: We also recorded if the flowers were bilaterally symmetrical “zygomorphic” or were radially symmetrical “actinomorphic”.
- Flower and inflorescence size: We searched for flower length and flower and inflorescence width (mm) for all species. When possible, we calculated the not found measurements with the help of online images and the software ImageJ.
- Flower number per plant: We compiled information about the number of flowers per plant for all species. However, this field was rare to find and we also used online images of the different species in order to calculate rough numbers of flowers per plant. We referenced all the filled fields in order to be able to follow the images that were used for these counts. It is important to note, that these numbers are not pretended to be the exact number of flowers per species but an approximate indicator of the reproductive investment for the different species that allow the macroecological analysis of this field.
- Ovule number: We searched for the number of ovules per flower for all the different species. The number of ovules of Asteraceae species are considered as the total number of ovules per capitulum. Many species were filled by genus or family level because the number of ovules in this taxonomic groups is considered to be mostly constant (e.g., Lamiaceae Boraginaceae or Apiaceae).
- Style length: The length of the style (mm) of the different species was also included. When possible, we calculated style length from images and illustrations on the online floras.
- Nectar provision: We recorded the presence and absence of nectar for all species. In addition, we also searched for microlitres and milligrams of nectar per flower and nectar concentration. In general terms, nectar data was rarely present and we try to

minimise the loss of information by filling some species at family level. For instance, Solanaceae species are described as nectarless, and species that belonged to this family were recorded with ‘absence’ of nectar.

- Pollen grains per flower: We recorded pollen grains per flower for all species but this field was rarely described in the literature. When just the pollen:ovule ratio was found we converted it back to pollen grains by multiplying by ovule number.

#### *Vegetative traits*

- Life form, life span and plant height: We divided the different plant species in 4 main categories: herbs, vines, shrubs and trees. Moreover, we also divided the species between short-lived species (annual, biennial and short-lived perennials) and perennial species (long-lived). Finally, we also searched for the average height (m) of the different species and annotated the maximum and minimum height when possible. We conducted the average between the maximum and minimum height to get an approximate average height of the species when the average was not indicated.

**Table S1.** List of the 28 plant-pollinator studies used to build the plant trait database. Each study is shown with the first author that conducted the study, number of networks or metawebs that contains, type of information that contains (weighted or unweighted), the structure (web or metaweb), year of publication and digital object identifier or permanent link for each study.

**Table S2.** Loadings and explained variance of the first three principal components from the phylogenetically informed principal component analysis for the full set of species (N = 1,506).

	PC1	PC2	PC3
Autonomous selfing	0.03	0.85	-0.51
Flowers per plant	0.75	-0.27	-0.24
Flower width	-0.67	-0.38	-0.30
Style length	-0.34	-0.37	-0.66
Ovule number	-0.53	0.00	-0.02
Plant height	0.56	-0.40	-0.46
Explained variation	26.72	25.08	19.17

**Table S3.** Loadings and explained variance of the first three principal components from the phylogenetically informed principal component analysis for the subset of sepcies with quantitative information of nectar and pollen.

	PC1	PC2	PC3
Autonomous selfing	0.19	0.76	0.35
Flowers per plant	-0.62	-0.35	0.45
Flower width	0.66	-0.44	-0.08
Style length	0.54	-0.42	0.13
Ovule number	0.60	0.00	-0.04
Plant height	-0.38	-0.52	0.53
Microlitres of Nectar per flower	0.51	0.06	0.66
Pollen per flower	0.16	-0.50	-0.11
Explained variation	23.40	21.67	14.36

**Table S4.** Statistical association of the different categorical variables to the first two principal components from the pPPCA with the full set of species. For each categorical trait and principal component, sum of squares, F-value and P-value are provided.

Functional traits	Sum Sq	F value	Pr(>F)	PC
Breeding system	304.59	119.50	0.00	PC1
Compatibility system	89.12	23.31	0.00	PC1
Lifespan	35.65	27.97	0.00	PC1
Life form	565.87	222.00	0.00	PC1
Flower shape	132.24	20.75	0.00	PC1
Flower symmetry	0.37	0.29	0.59	PC1
Nectar provision	0.38	0.29	0.59	PC1
Breeding system	304.59	119.50	0.00	PC2
Compatibility system	89.12	23.31	0.00	PC2
Lifespan	35.65	27.97	0.00	PC2
Life form	565.87	222.00	0.00	PC2
Flower shape	132.24	20.75	0.00	PC2
Flower symmetry	0.37	0.29	0.59	PC2
Nectar provision	0.38	0.29	0.59	PC2

**Table S5.** Phylogenetic signal for all quantitative traits. Phylogenetic signal of nectar and pollen traits was calculated for the imputed dataset of the subset of species with quantitative information of nectar and pollen.

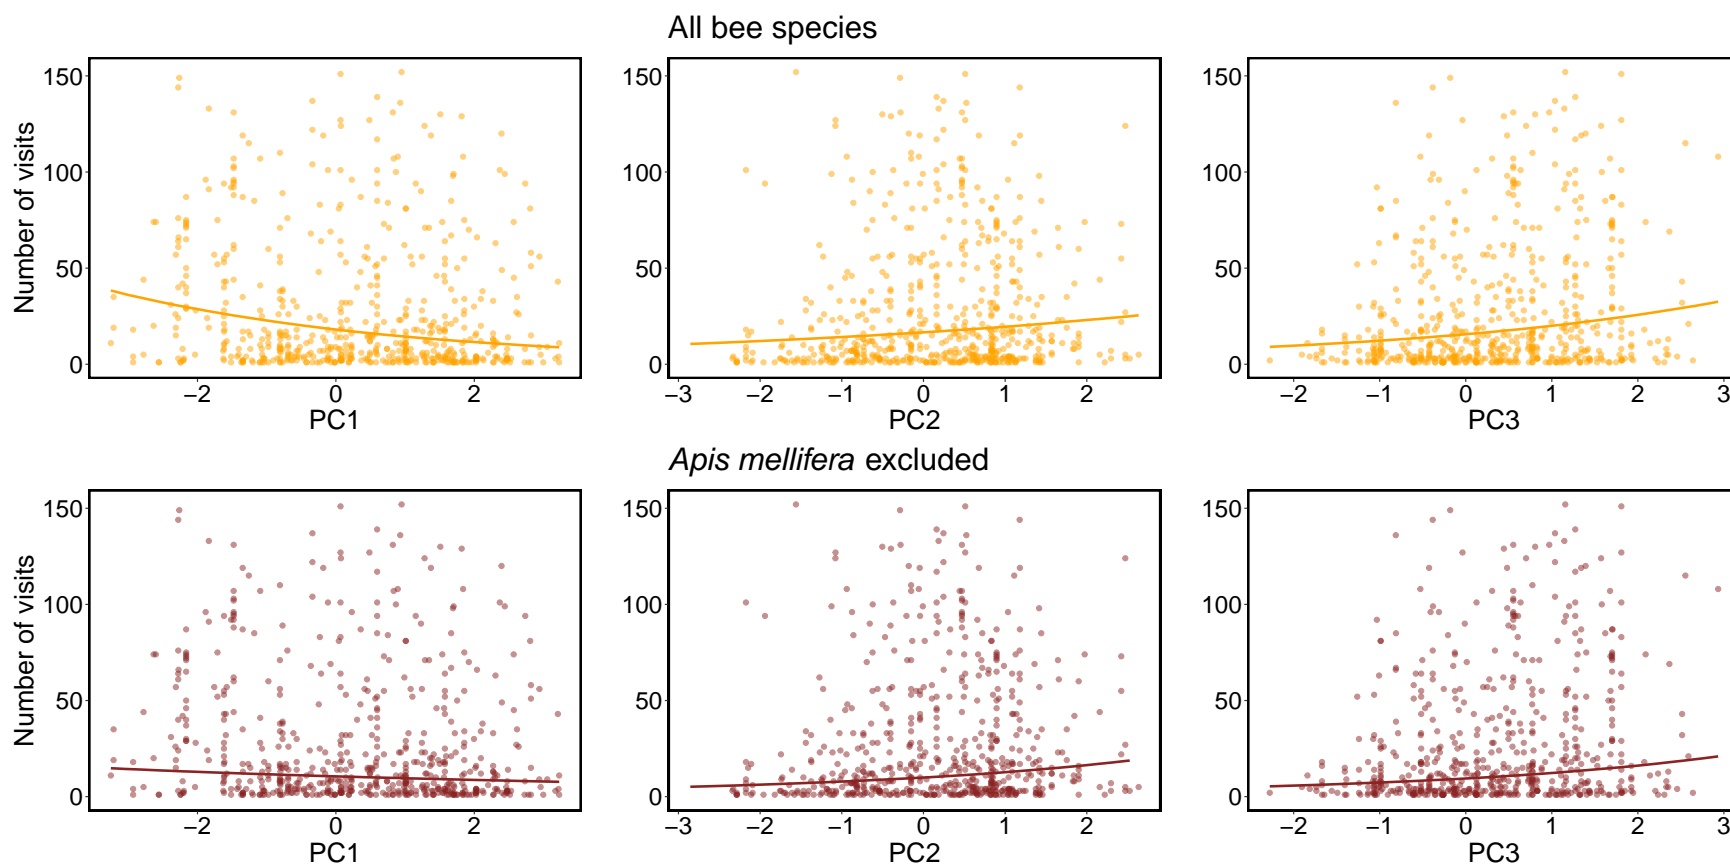

Functional traits	Lambda	P-value
Autonomous selfing	0.34	0.00
Flower number	0.69	0.00
Inflorescence width	0.57	0.00
Flower width	0.73	0.00
Flower length	0.75	0.00
Style length	0.49	0.00
Ovule number	1.00	0.00
Plant height	0.96	0.00
Nectar ( $\mu$ l) per flower	0.13	0.01
Nectar (mg) per flower	0.38	0.00
Nectar concentration (%)	0.61	0.00
Pollen grains per flower	0.84	0.00

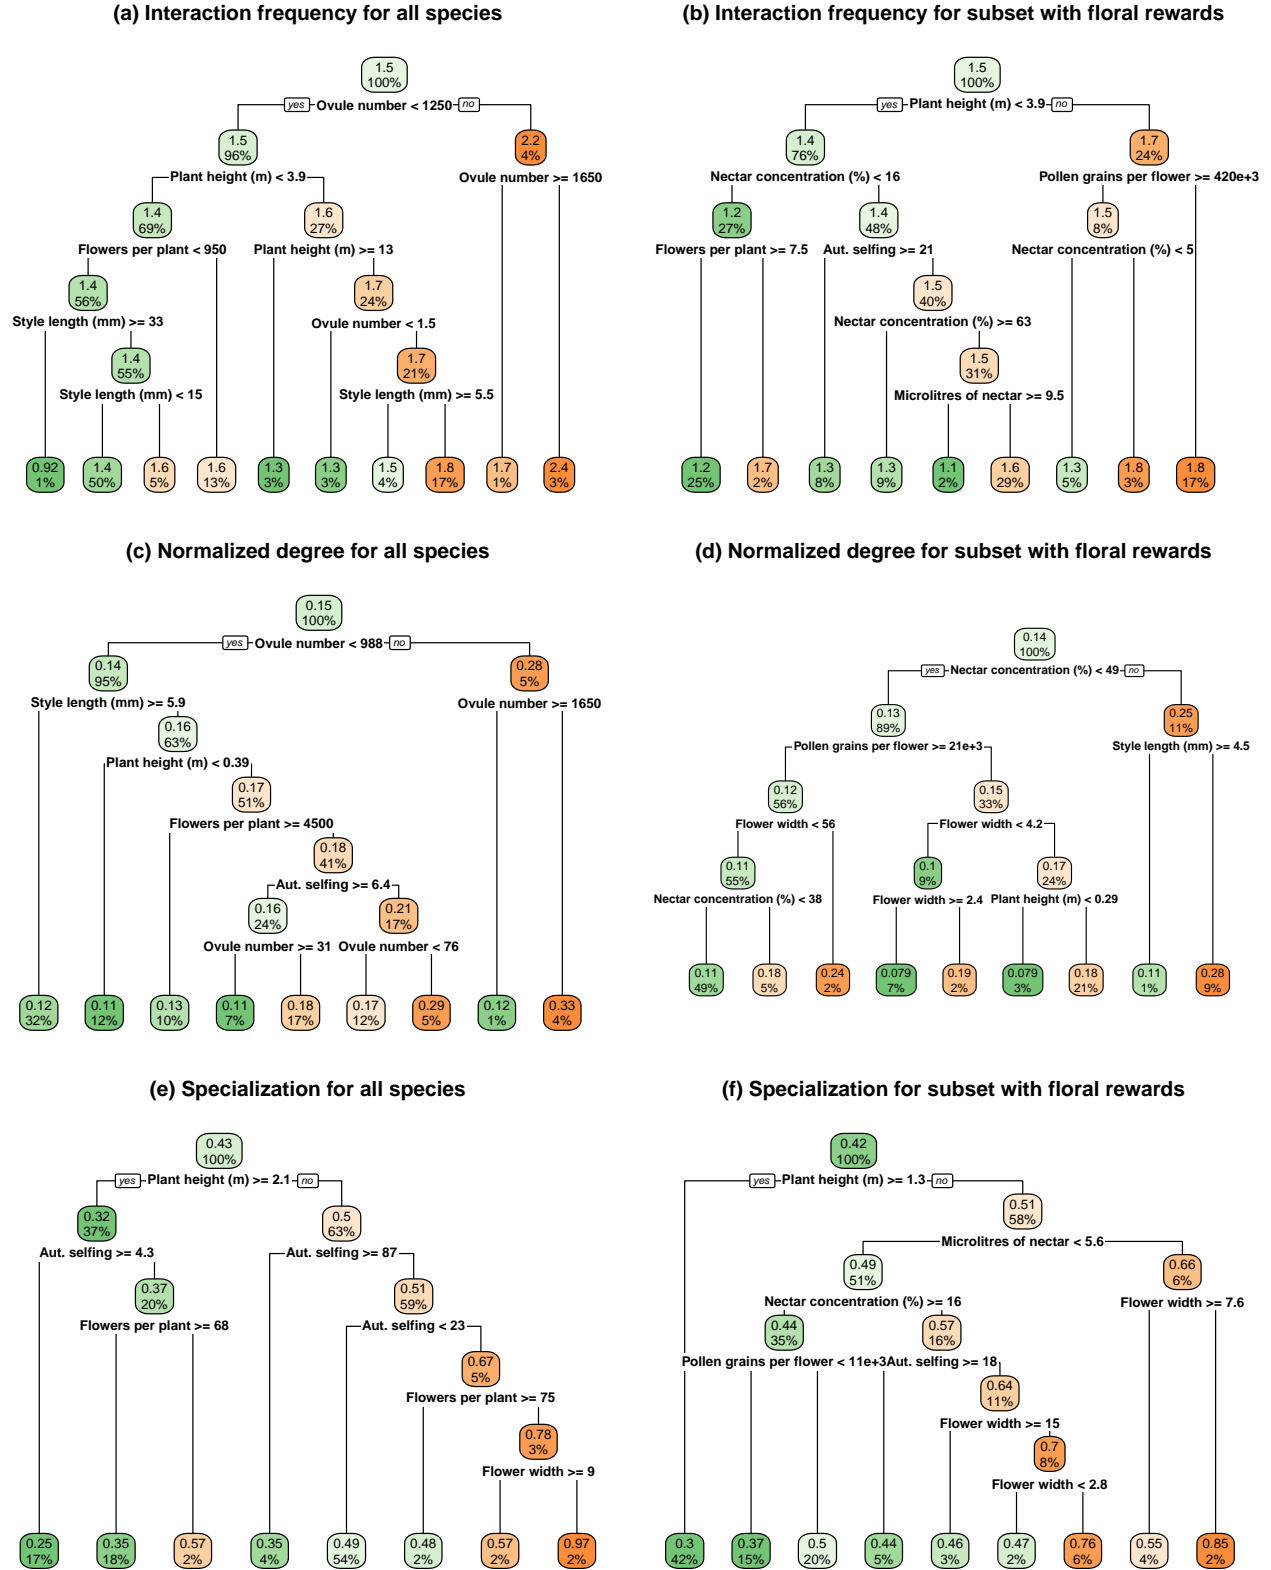

**Fig S1.** Percentage of present and missing values on the 20 traits compiled in this study (N = 1,506 species).

**Fig S2.** Phylogenetic informed principal component analysis for the species that did not have missing values (non-imputed dataset;  $N = 723$ ).

**Fig S3.** Fitted posterior estimates of the number of visits made by the functional group of Hymenoptera-Anthophila (bees) including (superior panel) and excluding (lower panel) *Apis mellifera* in relation to the main axes of trait variation (PC, PC2 and PC3).

**Fig S4.** Comparison of the regression tree analysis between the full set of species and the subset of species with floral rewards for each plant species level metric (interaction frequency, normalized degree and specialization).

**Fig S5.** Phylogenetically informed principal component analysis showing the trait relationship with principal components one and three (PC1 and PC3) for the full set of species (N = 1,506).

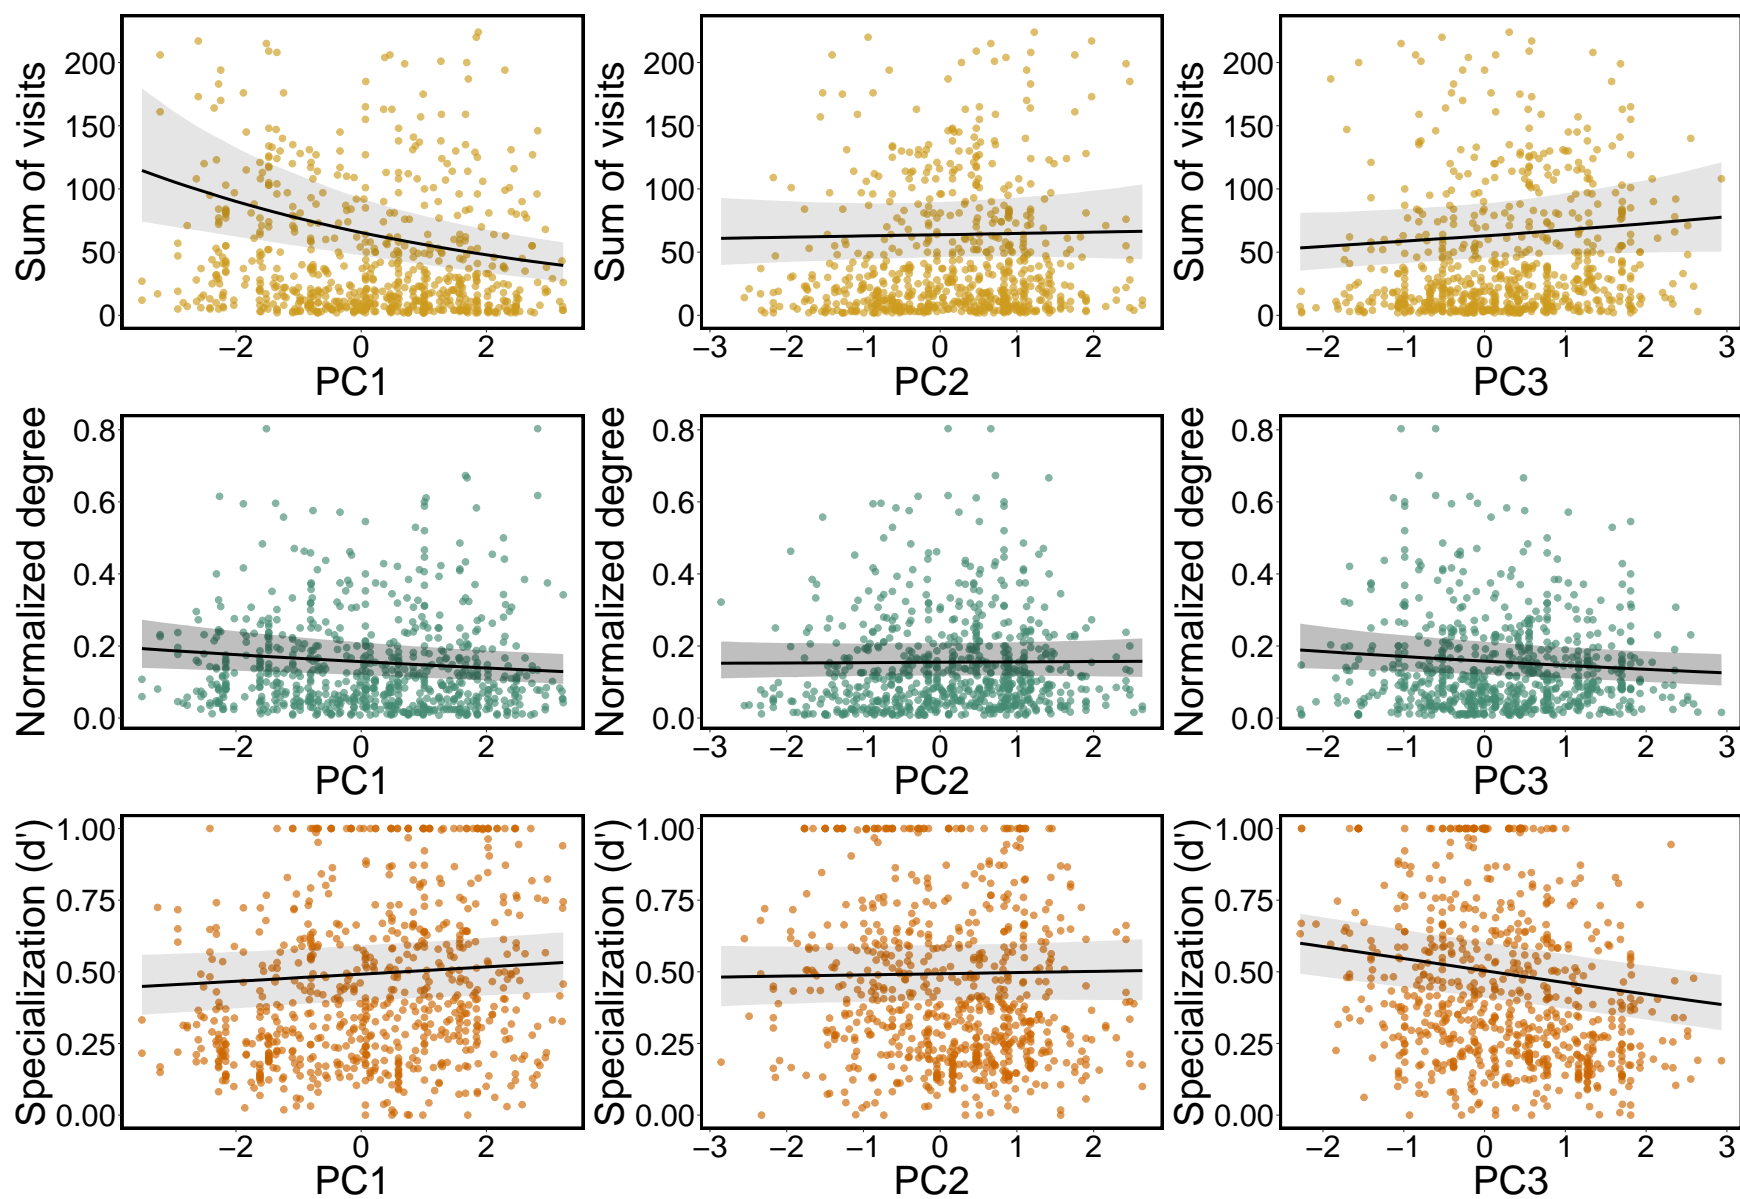

**Fig S6.** First two main principal components from the phylogenetic informed principal component analysis for the imputed dataset of the subset of species with quantitative information of nectar and pollen ( $N = 467$ ).

**Fig S7.** Statistical comparison of the different categories of the categorical traits on the main two axes of trait variation (pPCA with the full set of species). Categories that differ significantly are denoted with a different letter.

**Fig S8.** Fitted posterior estimates of the number of visits made by the different main visiting families of bees (Andrenidae, Apidae, Colletidae, Halictidae and Megachilidae) in relation to the main axes of trait variation (PC1, PC2 and PC3). We omitted in the plotting points over percentile 95 % percent due to extreme outliers.

**Fig S9.** Sum of visits per plant, normalized degree and speciliazation modelled in function of the first three main axes of trait variation.
